Understanding the HCG Diet

The HCG diet is a weight loss regimen that involves the administration of HCG hormone, typically through injections, combined with a very low-calorie diet (VLCD). The diet was popularized by Dr. A.T.W. Simeons in the 1950s, who claimed that the hormone could help mobilize fat stores, making it easier for individuals to lose weight. The standard protocol involves a loading phase, followed by a phase of strict calorie restriction, and then a maintenance phase.

How the HCG Diet Works

The HCG hormone is believed to play a role in regulating metabolism and appetite. When combined with a diet of around 500 to 800 calories per day, proponents argue that it helps the body utilize stored fat for energy. This drastic reduction in caloric intake typically leads to rapid weight loss, and many individuals report significant changes in their body composition.

Phases of the HCG Diet

The HCG diet consists of several phases:

- **Loading Phase:** This initial phase lasts two days, during which individuals consume high-calorie foods to prepare their bodies for the upcoming calorie restriction.
- **Weight Loss Phase:** This phase lasts anywhere from three to six weeks, during which participants adhere to a strict 500 to 800 calorie diet while continuing HCG hormone administration.
- **Maintenance Phase:** After achieving the desired weight loss, individuals gradually reintroduce calories over a three-week period to stabilize their new weight.
