2. Numerical Problems:

- Involve calculations based on real-world applications, such as finding the focal length of a lens or calculating the angle of refraction.

3. Graphical Problems:

- Students may be asked to analyze or interpret graphs related to light intensity, wavelength, or other optical properties.

Example Problems and Solutions

Here are a few examples of the types of problems and their solutions that can be found in this edition:

1. Problem: A ray of light strikes a glass surface at an angle of 30 degrees. What is the angle of refraction if the refractive index of glass is 1.5?

- Solution: Using Snell's law:
$$n_1 \sin(\theta_1) = n_2 \sin(\theta_2)$$
- Assuming n_1 (air) = 1.0, n_2 (glass) = 1.5, and $\theta_1 = 30$ degrees:
$$1.0 \sin(30) = 1.5 \sin(\theta_2)$$
- This leads to $\sin(\theta_2) = (0.5 / 1.5) = 0.333$, and thus $\theta_2 = \arcsin(0.333) \approx 19.5$ degrees.

2. Problem: Calculate the focal length of a concave lens with a radius of curvature of 20 cm.

- Solution: Using the lens maker's formula:
$$1/f = (n - 1) (1/R_1 - 1/R_2)$$
- For a concave lens, R_1 is negative, and R_2 is positive:

- Assume $n = 1.5$, $R_1 = -20 \text{ cm}$, $R_2 = \infty$.
- Therefore, $1/f = (1.5 - 1) (1/(-20) - 1/\infty) = 0.5 (-1/20) = -0.025$, so $f = -40 \text{ cm}$ (the lens is diverging).

3. Problem: In Young's double-slit experiment, if the distance between the slits is 0.5 mm and the screen is 2 m away, calculate the distance between the first and second bright fringes for light of wavelength 500 nm .

- Solution: Using the formula for fringe spacing:
- $\Delta y = (\lambda L) / d$
- Here, $\lambda = 500 \text{ nm} = 500 \times 10^{-9} \text{ m}$, $L = 2 \text{ m}$, and $d = 0.5 \times 10^{-3} \text{ m}$.
- $\Delta y = (500 \times 10^{-9} \times 2) / (0.5 \times 10^{-3}) = 0.002 \text{ m}$ or 2 mm .
